PRODUCT DEMAND PREDICTION WITH MACHINE LEARNING

REG NO:912421104050

NAME: K.TAMILOLI

PHASE 2 SUBMISSION DOCUMENT

INTRODUCTION:

A product company plans to offer discounts on its product during the upcoming holiday season. The company wants to find the price at which its product can be a better deal compared to its competitors. For this task, the company provided a dataset of past changes in sales based on price changes. You need to train a model that can predict the demand for the product in the market with different price segments.

The **dataset** that we have for this task contains data about:

- 1.the product id;
- 2. store id;
- 3.total price at which product was sold;
- 4. base price at which product was sold;
- 5. Units sold (quantity demanded);

Product Demand Prediction using Python: Example:

import pandas as pd import numpy as np import plotly.express as px import seaborn as sns import matplotlib.pyplot as plt from sklearn.model_selection import train_test_split from sklearn.tree import DecisionTreeRegressor

data =

pd.read_csv("https://raw.githubusercontent.com/amankharwal/Websit e-data/master/demand.csv")
data.head()

Output:

	ID	Store ID	Total Pric	e Base Price	Units Sold
0	1	8091	99.0375	111.8625	20
1	2	8091	99.0375	99.0375	28
2	3	8091	133.9500	133.9500	19
3	4	8091	133.9500	133.9500	44
4	5	8091	141.0750	141.0750	52

Content:

Consider incorporating time series forecasting techniques like ARIMA or Prophet to capture temporal patterns in demand data.

Data source:

To predict the future, statistics utilize data from the past. That's why statistical forecasting is often called *historical*. The common recommendation is collecting data on sales for at least two years.

Data collection and preprocessing:

- Data Collection: Data collection is the process of gathering and measuring information on variables of interest, in an established systematic fashion that enables one to answer stated research questions, test hypotheses, and evaluate outcomes.
- Data preprocessing: A component of <u>data preparation</u>, describes any type of processing performed on <u>raw data</u> to prepare it for another data processing procedure. It has traditionally been an important preliminary step for the <u>data mining</u> process.

MODEL SELECTION:

There are some regression algorithms are present

- Linear regression
- Random forest
- XG boost

FEATURE ENGINEERING:

Create new features or transform existing ones to capture valuable information.

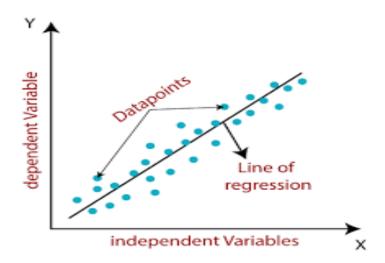

- Enhanced Model Performance
- Improved Interpretability
- Handling Non-linearity

Time-based features: These features capture trends and patterns over time. Examples include day of the week, month, year, and holidays.

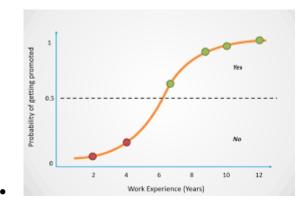

Store-based features: These features capture pharmacy-specific characteristics. Examples include the location of the pharmacy, the size of the pharmacy, and the customer demographics.

ADVANCED REGRESSION TECHNIQUES:

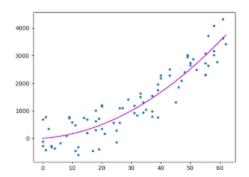

• Linear : Linear regression analysis is used to predict the value of a variable based on the value of another variable.

 Logistic: This type of statistical model (also known as logit model) is often used for classification and predictive analytics.
 Logistic regression estimates the probability of an event occurring, such as voted or didn't vote, based on a given dataset of independent variables.

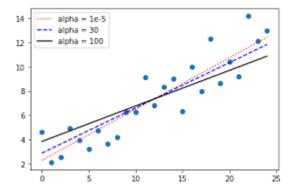

• Polynomial: Polynomial regression is a form of Linear regression where only due to the Non-linear relationship between dependent and independent variables.

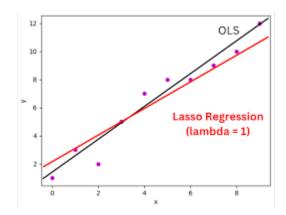

• Stepwise: Stepwise regression is the step-by-step iterative construction of a regression model that involves the selection of independent variables to be used in a final model.

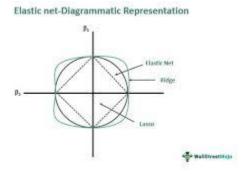

• Ridge: Ridge regression is a model tuning method that is used to analyse any data that suffers from multicollinearity.

• Lasso: LASSO regression, also known as L1 regularization, is a popular technique used in statistical modeling and machine learning to estimate the relationships between variables and make predictions.

• Elastic Net Regression: Elastic net linear regression uses the penalties from both the lasso and ridge techniques to regularize regression models.

ARIMA technique:

ARIMA is a method for forecasting or predicting future outcomes based on a historical time series. It is based on the

statistical concept of serial correlation, where past data points influence future data points.

Why is ARIMA good for forecasting? Advantages of ARIMA models:

ARIMA models can account for various patterns, such as linear or nonlinear trends, constant or varying volatility, and seasonal or non-seasonal fluctuations.

ARIMA Time-series Forecasting Methods:

Autoregressive integrated moving average (ARIMA) forecasting methods were popularized by G. E. P. Box and G. M. Jenkins in the 1970s. These techniques, often called the Box-Jenkins forecasting methodology, have the following steps:

- 1.Model identification and selection
- 2. Estimation of autoregressive (AR), integration or differencing
- 3.(I), and moving average (MA) parameters Model checking

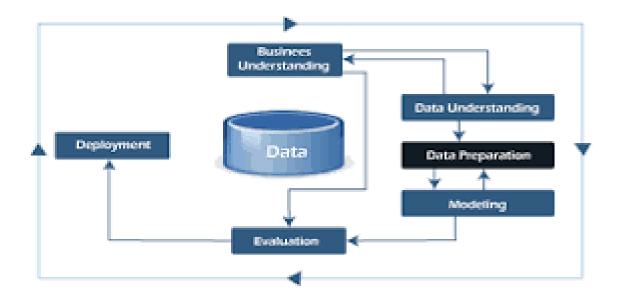

ARIMA is a univariate process. Current values of a data series are correlated with past values in the same series to produce the AR component, also known as p. Current values of a random error term are correlated with past values to produce the MA component, q. Mean and variance values of current and past data are assumed to be stationary, unchanged over time. If necessary, an I component (symbolized by d) is added to correct for a lack of stationarity through differencing.

In a nonseasonal ARIMA(p,d,q) model, p indicates the number or order of AR terms, d indicates the number or order of differences, and q indicates the number or order of MA terms. The p, d, and q parameters are integers equal to or greater than 0.

Data wrangling technique:

- Merging several data sources into one data-set for analysis.
- Identifying gaps or empty cells in data and either filling or removing them.
- Deleting irrelevant or unnecessary data.
- Identifying severe outliers in data and either explaining the inconsistencies or deleting them to facilitate analysis.

SARIMA (Seasonal ARIMA):

Extends ARIMA to handle seasonal patterns in data.

☐ Exponential Smoothing Methods:

These include Holt-Winters for capturing trends and seasonality.

Prophet:

Developed by Facebook, Prophet is useful for data with daily observations, holidays, and seasonality.

Deep Learning Models (e.g., LSTM and GRU):

Suitable for capturing complex temporal patterns, but they may require more data and computational resources.

Model Training:

Train the selected time series forecasting model using historical demand data. This involves estimating model parameters and seasonal components, if applicable.

Supervised learning:

Supervised learning, also known as supervised machine learning, is a subcategory of machine learning and artificial intelligence. It is defined by its use of labeled datasets to train algorithms that to classify data or predict outcomes accurately.

CLASSIFICATION:

Classification is a supervised machine learning method where the model tries to predict the correct label of a given input data. In classification, the model is fully trained using the training data, and then it is evaluated on test data before being used to perform prediction on new unseen data.

Hyper parameter optimization:

Hyperparameter optimization or tuning is the problem of choosing a set of optimal hyperparameters for a learning algorithm. A hyperparameter is a parameter whose value is used to control the learning process. By contrast, the values of other parameters (typically node weights) are learned.

Prophet:

```
# make an in-sample forecast
from pandas import read_csv
from pandas import to_datetime
from pandas import DataFrame
from fbprophet import Prophet
from matplotlib import pyplot
# load data
path =
'https://raw.githubusercontent.com/jbrownlee/Datasets/master/m
onthly-car-sales.csv'
df = read_csv(path, header=0)
# prepare expected column names
df.columns = ['ds', 'y']
df['ds']= to_datetime(df['ds'])
# define the model
model = Prophet()
# fit the model
model.fit(df)
# define the period for which we want a prediction
future = list()
for i in range(1, 13):
date = '1968-\%02d'\% i
```

```
future.append([date])
future = DataFrame(future)
future.columns = ['ds']
future['ds']= to_datetime(future['ds'])
# use the model to make a forecast
forecast = model.predict(future)
# summarize the forecast
print(forecast[['ds', 'yhat', 'yhat_lower', 'yhat_upper']].head())
# plot forecast
model.plot(forecast)
pyplot.show()
```

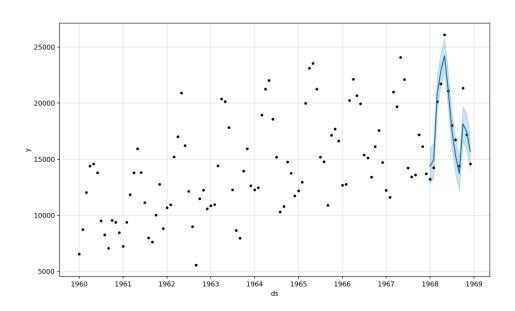

Running the example forecasts the last 12 months of the dataset.

The first five months of the prediction are reported and we can see that values are not too different from the actual sales values in the dataset.

EVALUATION:

• Mean Absolute Error(MAE) is the mean size of the mistakes in collected predictions. We know that an error basically is the absolute difference between the actual or true values and the values that are predicted. The absolute difference means that if the result has a negative sign, it is ignored.

What is Mean Squared Error or MSE

•The Mean Absolute Error is the squared mean of the difference between the actual values and predictable values.
